Data Processing R Training for NISR

Luiza Andrade, Leonardo Viotti & Rob Marty

Aug. 2018

- Introduction
- 2 Loading a data set
- 3 Exploring a data set
- 4 ID variables
- Subsetting
- 6 Factor variables
- Aggregating variables
- 8 Dropping Variables

Outline

- Introduction
- 2 Loading a data set
- Exploring a data set
- 4 ID variables
- Subsetting
- 6 Factor variables
- Aggregating variables
- 8 Dropping Variables
- Treating outliers
- Saving a data set
- Running a script from the master

Introduction

- In this session, you'll be introduced to some basic concepts of data cleaning in R. The contents covered are:
 - Importing data
 - Exploring a data set
 - Uniquely and fully indentifiable ID variables
 - Creating new variables
 - Dropping variables
 - Subsetting a data set
 - Dealing with factor variables
 - Aggregating variables
 - Treating outliers
- There are many other tasks that we usually perform as part of data cleaning that are beyond the scope of this session

Introduction

Before we start, let's make sure we're all set:

- Make sure the packages readstata13 and dplyr are listed in the packages vector of your Master script. If they are not installed (they should be!), install them.
- If you haven't yet in this session, run the Master script to load all the necessary packages and set file paths.
- Remeber to disable the PACKAGES switch in the Master if you already installed them. This will save you a lot of time.
- Open the script called Lab 3 in NISR R Training/Codes. We've provided you with some code to build upon that will save you some time during this session.

Introduction

Here's a shortcut if you missed the last session:

Outline

- Introduction
- 2 Loading a data set
- Exploring a data set
- 4 ID variables
- Subsetting
- 6 Factor variables
- Aggregating variables
- 8 Dropping Variables
- Treating outliers
- Saving a data set
- Running a script from the master

- In R, we usually save data in CSV format
- The .rds format is also a nice alternative, which we will cover soon, but it isn't the standard
- CSV files can be a lot lighter than binary files
- It is also possible to do version control of CSV files in .git
- On the other hand, the data they store is in a much simpler format, and we'll see some shortcomings of that soon
- To load a CSV data set, we use the read.csv() function

read.csv(file)

• **file**: is the path to the file you want to open, including its name and format (.csv)

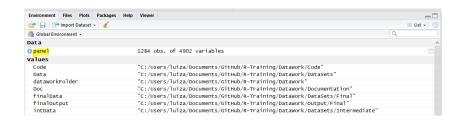

Exercise 1

Load the $lwh_panel.csv$ data set from "NISR R Training/Data/Raw". Create an object called panel with this data set.

• TIP: use the file.path() function and the rawData object created in the master to simplify the folder path.

```
# Load a CSV data set
panel <- read.csv(file.path(rawData, "lwh_panel.csv"))</pre>
```

If you look at the Environment pane, you'll be able to see this data set. Click on the blue arrow to see the list of variables.

- Note that R reads string variables as factors as default
- This format saves memory, but can be tricky if you actually want to use the variables as strings
- You can specify the option stringsAsFactors = FALSE to prevent R from turning strings into factors
- You can also simply recast any variables you want to be strings (as they'll probably be just a few) using the as.character() function

Loading a Stata data set

- You can also load a .dta file, i.e., a Stata data set, using the read.dta13() function.
- This function takes exactly the same argument as the read.csv function

Exercise 2

Use the function read.dta13() to load the endline_data_raw.dta data set from "NISR R Training/Data/Raw". Create an object called endline with this data set.

Loading a Stata data set

```
# Load the raw data from LWH endline
endline <- read.dta13(file.path(rawData,</pre>
                                  "endline data raw.dta"))
## Warning in read.dta13(file.path(rawData, "endline_data_raw.dta")):
##
     hhh change:
     Missing factor labels - no labels assigned.
##
     Set option generate.factors=T to generate labels.
##
## Warning in read.dta13(file.path(rawData, "endline_data_raw.dta")):
##
     decisionmaker:
##
     Duplicated factor levels detected - generating unique labels.
## Warning in read.dta13(file.path(rawData, "endline_data_raw.dta")):
     respondent main:
##
     Duplicated factor levels detected - generating unique labels.
##
## Warning in read.dta13(file.path(rawData, "endline_data_raw.dta")):
##
     respondent finance:
##
     Duplicated factor levels detected - generating unique labels.
## Warning in read.dta13(file.path(rawData, "endline_data_raw.dta")):
     ag10_16_1_1:
##
```

Loading a Stata data set

- In Stata, you can have different levels of a labelled variable with the same value label. That's not true for R factors, which is why all those warnings were created
- If you go to the Environment pane and click on the blue arrow, you'll see that string variables were imported as strings, and only labelled values were imported as factors
- If you scroll down on the variables list, you can also find some metadata such as variable labels, value labels and Stata formats saved as variables' attributes

Outline

- Introduction
- 2 Loading a data set
- Exploring a data set
- 4 ID variables
- Subsetting
- 6 Factor variables
- Aggregating variables
- Oropping Variables
- Treating outliers
- Saving a data set
- Running a script from the master

Some useful functions:

- class(): reports object type or type of data stored
- dim(): reports the size of each one of an object's dimension
- names(): returns the variable names of a data set
- str(): general information on a R object, similar to codebook in Stata

Exercise 3

Use some of the functions listed in the previous slides to explor the endline and panel objects.

• TIP: all of thesefunctions take a single argument, which is the object to be described.

```
# See objects' formats
  class(endline)
## [1] "data.frame"
  class(panel)
## [1] "data.frame"
  # How many observations and variables?
  dim(endline)
## [1] 1067 9198
  dim(panel)
   [1] 1284 4902
```

Outline

- Introduction
- 2 Loading a data set
- Exploring a data set
- 4 ID variables
- Subsetting
- 6 Factor variables
- Aggregating variables
- 8 Dropping Variables
- Treating outliers
- Saving a data set
- Running a script from the master

Desired properties of an ID variable: uniquely and fully identifying

- An ID variable cannot have duplicates
- An ID variable may never be missing
- The ID variable must be constant across a project
- The ID variable must be anonymous

Some useful functions to identify an ID variable in R

- unique(): displays unique occurrences in an object
- duplicated(): returns a boolean vector showing which observations of the object are duplicated
- length(): length of an object
- is.na(): returns a boolean vector showing which observations of the object have missing values

Exercise 4

Use one of the functions in the previous slide to tell if hh_code is a uniquely and fully identifying variables for the panel data set.

• TIP: All these functions take a single argument, which is the object we're testing.

• Uniquely identifying?

```
# See all unique values of hh_code
duplicated(panel$hh_code)

## [1] FALSE TRUE FALSE TRUE TRUE FALSE TRUE TRUE FALSE
## [12] FALSE TRUE TRUE TRUE FALSE TRUE TRUE FALSE
## Count duplicates
sum(duplicated(panel$hh_code))
```

```
## [1] 755
```

• Fully identifying?

```
# See all unique values of hh_code
is.na(panel$hh_code)
```

```
## [1] FALSE FALSE
```

```
# Count NAs
sum(is.na(panel$hh_code))
```

```
## [1] 0
```

Ok, that was a tricky question, as we already knew this is a panel data set. So let's try with what is a more credible ID variable

Exercise 5

Count the number of missing observations and duplicates values in the variables hh_code and year in the panel data set.

• TIP: you can use panel[,c("hh_code","year")] as the function's argument to test both variables at the same time. Note that this is still a single argument, but this time it's a data frame with two columns.

```
# Uniquely identifying?
sum(duplicated(panel[,c("hh_code","year")]))
## [1] 0
# Fully identifiying?
sum(is.na(panel$year))
## [1] 0
sum(is.na(panel[,c("hh_code","year")]))
## [1] 0
```

Exercise 6

Create new variable called id in the panel data set containing a uniquely and fully identifiable ID.

• TIP: To create a new variable in a data set, we simply assign a value to a column that doesn't year exist. You can make the ID unique by concatenating the year and the household ID.

```
# Create panel ID
  panel$id <- (panel$hh_code * 10000) + panel$year
  # Check properties
  sum(duplicated(panel$id))
## [1] 0
  sum(is.na(panel$id))
## [1] 0
  # Here's a shortcut similar to the isid variable in Stata
  length(unique(panel$id, na.rm = TRUE)) == length(panel$id)
## [1] TRUE
```

Outline

- Introduction
- 2 Loading a data set
- Exploring a data set
- 4 ID variables
- Subsetting
- 6 Factor variables
- Aggregating variables
- 8 Dropping Variables
- Treating outliers
- 10 Saving a data set
- Running a script from the master

- The panel has a lot more variables than we'll actually use for analysis
- Let's construct a new data set with only the variables we'll you
- For starters, we'll subset the panel data set and keep only some variables of interest
- These variables are already listed in the script we gave you
- But first let's take a look at how to find variables to select in a data set

The grep function is similar to the wildcard (*) in Stata: it looks for all elements of an object containing a certain pattern of strings.

grep(pattern, x): finds the elements of x that contain the pattern in pattern and returns a vector of indexes with their position

- pattern: the string expression you want to look for
- x: a vector of strings

Exercise 7

Create a vector called plot_area_vars containing the names of the variables with winsorized plot areas in seasons A, B and C:

- Use the grep() function to display the position index of all the variables in the panel data set whose name contains the expression area.
- Use the resulting vector from the grep() function to subset the vector of all variable names in the panel data frame.
- Oreate the plot_area_vars vector containing only the names of the winsorized plot area variables
 - TIP: these variables' names start with "w_".

- In the previous sessions, we talked about indexing and how we can use it to select specific rows and columns of objects
- Here's a quick recall:

```
## Select a column (variable) in a data frame:
# First column
panel[, 1]
# Select by name
panel[, "hh_code"]
panel$hh code
## Select elements in a vector
# Select one element in a vector
panel$hh_code[2]
# Select multiple elements in a vector
panel$hh_code[c(3,6,89)]
# Which is the same as
panel[c(3,6,89), "hh_code"]
```

 Now, let's use this information to subset our panel data frame and keep only the variables we have already listed

Exercise 8

Create a new object, called lwh, containing only the variables we selected from the panel data set.

Subsetting

```
# Select variables
 id vars
                   <- c("hh_code", "wave", "year", "treatment_hh",
                        "treatment_site", "site_code")
 demographic_vars <- c("gender_hhh", "age_hhh", "num_dependents", "read_and_write")</pre>
                   <- c("w gross vield a", "w gross vield b")
 vield vars
 food_vars
                   <- c("expend_food_yearly", "expend_food_lastweek", "wdds_score")
 income vars
                   <- names(panel)[28:37]
 plot_area_vars
                   <- c("w_area_plots_a", "w_area_plots_b", "w_area_plots_c")
 # Subset data
lwh <- panel[, c(id vars.</pre>
                  demographic_vars,
                  vield_vars,
                  food vars.
                  income vars.
                  plot_area_vars)]
  # Check result
 names(lwh)
## [1] "hh code"
                                                        "vear"
                                "wave"
## [4] "treatment hh"
                                "treatment_site"
                                                        "site_code"
  [7] "gender_hhh"
                                "age_hhh"
                                                        "num_dependents"
## [10] "read and write"
                                "w gross vield a"
                                                        "w gross vield b"
## [13] "expend_food_yearly"
                                "expend_food_lastweek"
                                                        "wdds_score"
## [16] "inc_livestock"
                                "inc_livestockprod"
                                                        "inc_on_farm"
```

[19] "inc non farm"

[25] "inc_other"

[22] "inc remittances"

[28] "w area plots c"

"inc sale land"

"w_area_plots_b"

"inc pension"

"inc rent land"

"w_area_plots_a"

"inc int div"

Outline

- Introduction
- 2 Loading a data set
- Exploring a data set
- 4 ID variables
- Subsetting
- 6 Factor variables
- Aggregating variables
- Oropping Variables
- Treating outliers
- 10 Saving a data set
- Running a script from the master

Creating a factor

Let's take a look at the variable gender_hhh in the lwh data set:

```
# Tabulate gender of household head
table(panel$gender_hhh)
```

```
## 0 1
## 413 784
```

This is supposed to be categorical variable, but for now it's just numeric.

Creating a factor

To create a factor variable, we use the factor function:

factor(x, levels, labels): turns numeric or string vector x into a factor vector * x: the vector you want to turn into a factor * levels: a vector containing the possible values of * * labels: a vector of strings containing the labels you want to apply to your factor variable

Exercise 9

Replace the variable gender_hhh in the 1wh data set by a factor. Label the factor so that 0 is "Female" and 1 is "Male".

• TIP: the first string in the labels argument will be applied to the first value in the levels argument, the second to the second and so on.

Creating a factor

```
# The numeric variable
  table(lwh$gender_hhh)
##
##
     0 1
## 413 784
  # Turn numeric variable into factor
  lwh$gender_hhh <- factor(lwh$gender_hhh,</pre>
                            levels = c(0, 1),
                            labels = c("Female", "Male"))
  # The factor variable
  table(lwh$gender_hhh)
```

```
## ## Female Male
## 413 784
```

Exploring factors

Here are a few useful functions to explore factors:

- str(): we've already seen this function. When using it with factors is that is shows the number and some variable labels
- levels(): displays the different values of a factor variable
- table(): displays a frequency table per level of a factor variable

Exercise 10

- Use the functions listed above to explore the wave variable in the lwh data set.
- (challenge) Use the table() function to see the year of each wave. Use the help if necessary.

Exploring factors

```
# First look at the variable
 str(lwh$save)
   NULL.
 # List all levels
 levels(lwh$wave)
## [1] "Baseline" "Endline" "FUP1&2"
                                         "FUP3"
                                                    "FUP4"
 # Observations per level
 table(lwh$wave)
##
## Baseline Endline
                       FUP1&2
                                  FUP3
                                            FUP4
        213
                 307
                          126
                                   345
                                            293
 # Year of each wave
 table(lwh$wave, lwh$vear)
              2012 2013 2014 2016 2018
```

0

0

0

0 126 0 345 307

Baseline 213 Endline

FUP1&2

FUP3

FUP4

##

Ordering factors

- The wave variable's levels are not ordered correctly
- That's because R creates the number underlying a factor in alphabetical order
- However, that can be misleading, specially if we're using this variable for tables and graphs
- If we want the levels of a factor to be in an specific order, we need to set the argument ordered of the factor() function to TRUE
- This will tell R that the order of the levels is exactly the same as the one specified in the levels argument

Ordering factors

Exercise 11

Make the wave variable in the lwh dataset an ordered factor, ordering them by the year in which they happened

Ordering factors

```
##
##
          2012 2013 2014 2016 2018
##
   Baseline 213
##
   FUP1&2
            0 126 0
                0 345 0
   FUP3 0
##
##
   FUP4
            0 0 0 293
   Endline
                    0
                       Ω
                         307
##
```

Outline

- Introduction
- 2 Loading a data set
- Exploring a data set
- 4 ID variables
- Subsetting
- 6 Factor variables
- Aggregating variables
- Oropping Variables
- Treating outliers
- Saving a data set
- Running a script from the master

- For our analysis in the next sessions, we will not use the disaggregated income variables
- We'll rather be interested in the total income of a household
- To calculate the total income, we'll use the rowSums() function, equivalent to rowtotal in Stata
- rowSums() is part of a function family that allows you to aggregate row and columns of a data set
- They all have the same syntax

rowSums(x, na.rm = FALSE): sums selected variables in all rows of a
data set

- x: the two-dimensional object whose columns you want to add
- na.rm: by default, when any of the values you're trying to add are
 missing, the result will be a missing value. Make this argument TRUE
 for R to treat missing values as zero in the sum

Exercise 12

Create a variable called income_total in the lwh data set containing the sum of all the income variables you listed in the income_vars vector.

Exercise 13

Create a variable called income_total in the lwh data set containing the sum of all the income variables you listed in the income_vars vector.

```
# List variables
income vars
    [1] "inc livestock"
                             "inc livestockprod" "inc on farm"
    [4] "inc non farm"
                              "inc rent land"
                                                   "inc sale land"
##
    [7] "inc remittances"
                             "inc int div"
                                                   "inc pension"
##
   [10] "inc other"
# Add columns
lwh$income total <-</pre>
  rowSums(lwh[, income_vars],
          na.rm = TRUE)
```

Outline

- Introduction
- 2 Loading a data set
- Exploring a data set
- 4 ID variables
- Subsetting
- 6 Factor variables
- Aggregating variables
- 8 Dropping Variables
- Treating outliers
- Saving a data set
- Running a script from the master

Dropping variables

Now, let's remove the disaggregated income variables from data set, since we're using them anymore.

The easiest way to remove variables from a data set is to make those variables NULL. Like this:

```
dataset$variable <- NULL
```

To do this for a series of variables at the same time, you can select them by their names. Like this:

```
dataset[, c("var1", "var2", "var3")] <- NULL
```

Dropping variables

Exercise 14

Remove all of the raw income variables listed in the income_vars vector from the lwh data data set.

Dropping variables

Exercise 15

Remove all of the raw income variables listed in the income_vars vector from the lwh data data set.

```
# Remove income variables
lwh[, income_vars] <- NULL</pre>
```

Outline

- Introduction
- 2 Loading a data set
- Exploring a data set
- 4 ID variables
- Subsetting
- 6 Factor variables
- Aggregating variables
- ® Dropping Variables
- Treating outliers
- Saving a data set
- Running a script from the master

Treating outliers

- There are different ways to treat outliers and there's not a single best method for doing it
- In the end, this is an analysis question, it is good to avoid droping a whole observation from your data set because of an outlier in a single variable

Winsorizing

To winsorize a variable means to replace all observations with value above (or below) a given percentile by the value of that percentile, therefore capping the distribution of the resulting variable.

There are a few different functions that perform winsorization in R, but we'll do it here by writing our own.

As we've seen in session 2, you can create functions in R using a function called function(). In the next slide, we'll give you some code to create a function that

- Calculates the value of the 90th percentile of its argument
- Replaces all values above this percentile in its argument by the 90th percentile
- Returns the resulting variable

Winsorizing

```
# Create a function to winsorize at the 90th percentile
winsor <- function(x) {
    x[x > quantile(x, 0.9, na.rm = T)] <-
        quantile(x, 0.9, na.rm = T)
    return(x)
}

# Create winsorized income
lwh$income_total_win <- winsor(lwh$income_total)</pre>
```

Trimming

To trim a variable means to replace all observation above a certain value (usually a given percentile) with missing values. It's particularly useful to create non-distorted graphs.

Exercise 16

Edit the winsor() function created earlier to create a new function that trims observations:

- Instead of replacing the values with the 90th quantile, replace it with "NA"
- Call this function trim
- Use this function to trim the income_total variable in the lwh data set and create a new variable called income_total_trim

Trimming

```
# Create the trim function
trim <- function(x) {
   x[x > quantile(x, 0.9, na.rm = T)] <- NA
   return(x)
}

# Trim income
lwh$income_total_trim <- trim(lwh$income_total)</pre>
```

Treating outliers

```
# Compare variables
 summary(lwh$income total)
##
     Min. 1st Qu. Median
                            Mean 3rd Qu. Max.
##
        0
            15240
                   52800
                           88549
                                 130740 441000
 summary(lwh$income total win)
     Min. 1st Qu. Median
##
                            Mean 3rd Qu. Max.
            15240

Outline

- Introduction
- 2 Loading a data set
- Exploring a data set
- 4 ID variables
- Subsetting
- 6 Factor variables
- Aggregating variables
- 8 Dropping Variables
- Treating outliers
- Saving a data set
- Running a script from the master

Saving a data set as CSV

- As mentioned before, R data sets are usually save as CSVs
- To save a data set, we use the write.csv() function:

write.csv(x, file, row.names = TRUE)

- x: the object (usually a data frame) you want to export to CSV
- file: the file path to where you want to save it, including the file name and the format (".csv")
- row.names: by default, R adds a column to the CSV file with the names (or numbers) of the rows in the data frame. Set it to FALSE if you don't want that column to be exported

Saving a data set as CSV

Exercise 17

Save the lwh data set to NISR R Training/Data/Final.

• TIP: Use the file.path() function and the object finalData created in the master to simplify the folder path.

Saving a data set as CSV

Saving a data set in R format

- The main issue, at least for now, of saving a data set as CSV is that when you open it again all strings and factors will be imported in the same format (either strings or factors, depending on how you set the stringsAsFactors option).
- One other issue is that factors will be labelled in alphabetical order, so any ordering of factors that you may have created will be lost

```
# Save the lwh data set as .RDS
save(lwh,
    file = file.path(finalData, "lwh_clean.rds"))
```

Outline

- Introduction
- 2 Loading a data set
- Exploring a data set
- 4 ID variables
- Subsetting
- 6 Factor variables
- Aggregating variables
- Oropping Variables
- Treating outliers
- 10 Saving a data set
- Running a script from the master

Running a script from the master

Exercise 18

- Save this script
- Add a switch for Lab3 in your master
- Oreate an if statement that runs this script if the switch is on. To do this, use the source() function, which is equivalent to the do function in Stata.
- TIP: just like the do function in Stata, the only argumento of the source() function is the complete file path to your script. Don't forget to you explicit and dynamic file paths!
